Strategic Enterprise Application Integration

By Alan Perkins
Chief Solutions Architect
ASG Federal

The biggest problem facing CIO's today is their existing applications.

Enterprise Application Development is the Problem

The legacy system problem has many symptoms: systems that don’t work together, too much data and not enough information; incompatible and incorrect data; and excessive maintenance costs. 70% to 90% of an organization's IS budget is spent typically on current applications. There are lots of reasons for this, but the primary cause is the way the applications were developed:

- Independently as stand-alone, "stove-pipe" systems -- not designed to be interoperable.
- Not based upon a single enterprise standard
- Without a common data architecture to ensure data sharing
- In unstructured programming languages
- Poorly documented if documented at all
- Designed to reflect developers interpretation of business requirements ten years, twenty years, or even longer ago

Since they were first implemented, most legacy applications have been patched and modified over and over to fix errors and respond to changing requirements until the IS staff is fearful of making any changes because they cannot predict results.

Compounding the problem is the variety of technologies that exists in most organizations. In addition to multiple programming languages and methods, there are multiple platforms, operating systems, data management systems, and communication protocols.

More recently, business and competitive pressures have caused enterprises to install multiple, single function commercial packages that further complicated an already serious problem.

Most CIO's recognized long ago that this is not an optimum environment for effective information management and that something must be done. The most common solution tried over the years has been developing interfaces between the applications. These included interface programs and interface data stores. This worked fairly well when only a few interfaces were needed. But as the number of interfaces grew, the result was additional maintenance problems and what the Gartner Group calls "inter-application spaghetti." Even today many organizations are still trying to integrate their applications through interfaces -- without much success.

Other organizations are trying to solve their legacy application problems using a number of relatively new approaches including:
• Replacing legacy systems with integrated COTS packages (like Baan, PeopleSoft, and SAP)
• Developing data and information warehouses
• Establishing central operational data stores or data clearinghouses
• Implementing Enterprise Portals
• Using Middleware
• Using XML
• Reengineering all applications to a single architecture

All of these approaches have value and some will even provide at least temporary benefit. However, unless they are business-driven and model-based they are more likely to further compound the problems than provide a solution.

**Strategic Enterprise Application Integration is the solution.**

This paper describes a method that unifies these approaches as well as other best practices and techniques. Strategic Application Integration really works! It not only solves today's problems but also helps prepare our clients for success in the future.

Strategic Enterprise Application Integration reduces maintenance overhead while providing better customer service and quality information systems. The ultimate goals of Strategic Enterprise Application Integration are shared, non-redundant data, trusted strategic information, and shared reusable software components.

Strategic Enterprise Application Integration is flexible enough to work in any Information Technology environment, yet rigorous and disciplined enough to produce results consistently.

Strategic Enterprise Application Integration solutions differ from enterprise to enterprise depending upon their business requirements, the nature and seriousness of their problem, and the skills and availability of their staff. Most variations include the following activities:

• Define and document strategic enterprise business drivers
• Reverse engineer existing applications and databases to document and model the existing application architecture (it exists whether or not it is documented)
• Define and model business information and data requirements (current and future)
• Define and model business functional requirements (current and future)
• Compare application architecture models with requirements and perform gap analysis
• Choose appropriate integration method(s)

It is really important to know what to integrate and why before deciding how. Integration options include:

• Integrate current applications (data and function) that meet requirements
  – Reengineer using new technologies
  – Use middleware
• Remove redundant and unnecessary applications
• Develop or purchase applications to meet new/changed requirements

Strategic Enterprise Application Integration does not happen all at once. It is a gradual, logical, repeatable process that transitions an enterprise from poorly integrated, sub-standard applications to business-driven, model-based, quality integrated applications that exactly meet enterprise data and information needs. It can take a long time if the organization's problem is severe. However, improvement and return on investment begin almost immediately.

**Enterprise Architecture Makes It Possible**

The key to successful Strategic Enterprise Application Integration is Enterprise Architecture. An enterprise architecture links an enterprise's strategic plan and performance plans ("business architecture") with its enterprise information architecture, enterprise service component (systems
and applications) architecture and enterprise technical architecture. A well-documented architecture is a logical organization of information pertaining to the following multi-level, multi-dimensional, enterprise-wide elements:

- Strategic goals, objectives, and strategies
- Business rules and measures
- Information requirements
- Processes, systems and applications
- Relationships between architecture elements
- Technology infrastructure

Enterprise architecture also contains guidelines, standards, policies and business rules that define the enterprise’s software engineering environment.

Every enterprise has an architecture. However, it is usually undocumented and the elements are inconsistent. Most likely some of the architecture elements are embodied in strategic and performance plans, published and unpublished policies and procedures, and system documentation. Unfortunately, there are also a lot of enterprise architecture elements that are embedded in software application code, and even more that only exist as employee “tribal knowledge.” An undocumented enterprise architecture is an unmanaged enterprise architecture and is a sure recipe for chaos.

On the other hand, a fully documented enterprise architecture can be used to enable successful Strategic Enterprise Application Engineering and also accomplish the following:

- Facilitate quality software engineering and enterprise change management by linking strategic requirements to systems that support them and by linking the business model to application designs
- Enable strategic information to be consistently and accurately derived from operational data
- Promote data sharing, thus reducing data redundancy and reducing maintenance costs
- Improve productivity through component development, management and reuse
- Reduce software development cycle time
- Evaluate commercial products and services
- Share information with customers and business partners

In order to establish an enterprise architecture that can be used to gain these benefits, it must be “engineered.” This requires rigorous and repeatable process that is strategically-driven, information-centric, model-based, and technology independent. It also requires tools that fully support the approach. The author’s papers, “Enterprise Architecture Engineering” and “Critical Success Factors for Enterprise Architecture Engineering” describe this process.

**XML Makes It Likely**

XML (eXtensible Markup Language) is becoming the new standard language for building Corporate Portals, integrating legacy databases, and facilitating E2E (Enterprise to Enterprise) and B2B (Business to Business) data communication.

XML will be the successor to HTML (HyperText Markup Language) for the Internet, Intranets, and for secure Extranets between customers, suppliers and business partners. XML incorporates metadata in any document, to define the content and structure of that document and any associated (or linked) resources. It has the potential to transform the integration of structured data (such as in legacy files or relational databases) with unstructured data (such as in text
documents and reports, graphics and images, audio and video resources, and web pages). XML will be a significant technology for the deployment of Data Warehouses and Enterprise Portals.

XML uses the eXtensible Style Language (XSL) and the eXtensible Linking Language (XLL) to achieve this integration. XML, XSL and XLL allow the easy integration of dissimilar systems for multiple worldwide customers and suppliers in any industry. It permits the ready integration of those systems, regardless of whether they are legacy systems and databases, Electronic Data Interchange (EDI) systems or Electronic Commerce. It represents the future direction of metadata and the important role that data administration will take in systems development in the years ahead.

XML assumes that metadata has already been defined. This is necessary not only for the new systems, but also for the legacy systems and databases that need to be integrated with those new systems. XML will enable this integration to be carried out dynamically.

Many products have been released recently to support the development of XML applications and XML databases for use in Enterprise Application Integration.

**The Right Tools Make It Possible**

Automated tools are the enabling technology that allows Strategic Enterprise Application Integration, including data integration, software component reuse, and rapid change management, to be realized. Exceptional software component development and management tools as well as tools for application and data integration are available from multiple sources. The minimum requirements for a tool suite are that it allows enterprise needs and measures to be linked directly to a strategic information model, enterprise data dictionary, legacy data base models, data integration and transformation process models, and data warehouse and data mart database design models -- all in a single repository. This linkage enables consistently successful development and implementation of high-quality data warehouses and data marts. It also allows quick reaction to changes in environment, policy, or customer requirements.

An effective tool suite provides the capability to document an enterprise’s multi-level, strategic plans, and link them to appropriate performance measures. More importantly, it also allows information requirements that support an enterprise’s strategic plans and performance measures to be modeled and translated into database, data mart, data warehouse, decision support system (DSS), and executive information system (EIS) models and designs. These designs can then be developed and implemented, ensuring that the enterprise’s information systems meet its information needs.

**Summary**

Strategic Enterprise Application Integration method and tools result in useable, effective information management systems that exactly meet the needs of your enterprise, public or private, large or small. This approach lets you immediately start to realize real value from your corporate information resources while improving your management of those resources.

Alan Perkins has been a Systems Analyst on the White House staff, Director of the US Army Data Processing School in Germany, Vice President of R&D for a virtual corporation, Vice President of Consulting for a software engineering tools company, and General Manager of a high-tech consulting firm. He has provided information and enterprise management consulting to numerous companies, associations and government agencies.

Mr. Perkins specializes in Enterprise Architecture Engineering. He helps clients quickly engineer enterprise architectures that are actionable and adaptable. His approach results in architectures that enable and facilitate enterprise initiatives such as Corporate Portals, Enterprise Data Warehouses, Enterprise Application Integration, Software Component Engineering, etc.
